Investigation of Benefits from Organic Management Alternatives Using DNDC Model Simulations for Developing Sustainable Practices in Texas Rice Production. Aditi Pandey ¹ , Fugen Dou ² , Cristine L Morgan ¹ Department of Soil and Crop Sciences, Texas A&M University, 2474 TAMU, College Station, TX 77843, USA ^{TEXAS A&M} ¹ Department of Soil and Crop Sciences, Texas A&M University, 2474 TAMU, College Station, TX 77843, USA ² Texas A&M AgriLife Research & Extension Center at Beaumont, 1509 Agrie Dr. Beaumont, TX 77713, USA				
Introduction	Results and Discussion			
 Delineating a holistic set of sustainable practices catered toward the welfare of farmers and the local community has become critical for maintaining and enhancing soil ecosystem services. Organic rice production management options need to be evaluated and compared to conventional systems. 	Grain Yield in Organic Systems 10000 $(r-e_{1}) 000$ $(r-e_{1}) 000$ $(r-e_{1$	a. model has accurately simulated rice ecosystem emissions to predict lo **q**-term benefits from rice management strategies in Japan and China (Fumoto et. al., 2008; Zhao et al., 2016)

Organic and conventional rice production systems were compared using DNDC simulations

he DNDC model was optimized and verified against data from a greenhouse trial conducted in 2015 using hybrid cultivar XL753 and 6 N rates of Urea and manure

Factors of variation studied: Methane emission Grain yield Soil organic carbon

kg N ha⁻¹ Fig 2. Grain yield observed and simulated for organic system using manure as N source

 $r^2 = 0.99$ Grain Yield in Conventional Systems

kg N ha⁻¹

Fig 3. Grain yield observed and simulated for conventional

Fig 7. Modeled and observed methane emissions from the organic and conventional systems and observed flux from the greenhouse study for: a. 0 (control) ; b.50; c.100; d. 150 ; e. 200 ; and f. 250 kg N ha⁻¹

- Methane emission is consistently higher for the Organic compared to the Conventional Systems (Fig 7.)
- Control had the lowest emissions (Fig 7.)
- Manura provides additional source of carbon in the

50 200 250 kg N ha⁻¹ Fig 4. Soil Organic Carbon values post harvest

Organic Rice Ecosystem Services Concepts

- Linking Natural Capital with Socio-Ecological **Capital** (Fig 6.)
- Linking indicators Identified: Soil N concentrations, SOC content, Soil Eh (Fig 6.)
- **Ecosystem Services**: provision of food, provision of raw materials and filtering of nutrients (Fig 6.)
- **Benefit Transfer Mechanism**: marketable product yield, yield factor of available cultivable land and cost reductions from reduced fertilizer input (Fig 6.)

	 system using urea as N source Manure provides additional source of carbon in the system 	
Research Objectives	Material and Methods	Future Research
	Denitrification and Decomposition (DNDC) is a process-based model that simulates biogeochemical processes of	Challenges

Fig 1. Map of Texas A&M Agrilife Extension sites and Beaumont, TX.

2. Compare fluctuations in methane emissions between organic and conventional rice production systems using six application rates of fertilizer and manure each

- 3. Predict the capacity of carbon sequestration based on the soil organic carbon pool (non-labile) and evaluate its net capacity as a carbon sink
- 4. Employ the linking indicators to evaluate the status

carbon and nitrogen for agricultural ecosystems.

σ

- Most Sensitive Factor (MSF) analysis was used to create a range of acceptable values for maximum biomass, soil organic carbon, microbial activity index, and soil pH
- Root, stem, leaf and grain fractions were collected and analysed for total carbon and nitrogen using standardized method of analysis
- Soil total carbon and nitrogen values were determined
- Temperature and precipitation data were adjusted to fit the environment of the greenhouse over normal field trials

II. Model was verified by comparing to a 2015 greenhouse study

III. Organic Rice Ecosystem Services. A conceptual model was created (Fig. 6).

- Observations for CH₄ emission from the greenhouse study were not made daily due to high cost of analysis.
- Collection and compilation of data for climate inside and outside the greenhouse should include observed daily air temperature and solar radiation.
- Determination of soil microbial population to better fit the DNDC index using laboratory analysis is also a requirement

Future Research Objectives

- For future optimization of the study for Texas, field data must be collected on soil properties
- Collaboration prospective with National Institute of Agroenvironmental Sciences, Tsukuba, Japan to share their version of DNDC-Rice
- Present study has the capacity to be used for a regional analysis of the Texas coastline currently being used for rice production

of ecosystem services from adopting the organic sustainable alternatives
