Introduction

Introgression of genes from exotic germplasm and wild relatives into elite inbred lines is essential to increased genetic variation and continued improvement in yield and stress tolerance.

Aflatoxin, produced by *Aspergillus flavus*, is one of the major diseases in southern United States and other parts of the world under warm climate. Aflatoxin contamination in grains can affect the marketability of the harvested corn and poses serious health problems in human and livestock. Use of resistant germplasm is a most effective and economical approach to reduce aflatoxin contamination.

Objective

To evaluate aflatoxin resistance and grain yield of the hybrids of the inbred lines selected from tropical x temperate corn and temperate corn x teosinte breeding populations.

Materials & Methods

Agronomic Evaluation:

- Fifty hybrids were evaluated for yield and aflatoxin content in seven locations in 2014 and six in 2015.
- Evaluated hybrids included 43 experimental hybrids and seven commercial hybrids and belong to five groups: Group 1 – ANTIGO, Group 2 – Early hybrids, Group 3 – Mid-full season, Group 4 – Hybrids of the lines from corn x teosinte crosses, and Group 5 – Commercial checks. All hybrids in the first three groups were made by lines developed from tropical x temperate breeding populations.

- Experiment sites were located in northern, central and southern part of Texas (Figure 1).

Aflatoxin Inoculation:

- Plants were inoculated with high toxin-producing strain of *A. flavus* with silk channel method at Halfway and ground kernel inoculation at Corpus Christi (Figure 2).
- In each plot, at least ten inoculated ears were harvested and grain samples were analyzed for aflatoxin.

Results

Figure 3. Average aflatoxin content (top) and grain yield (bottom) reported across diverse locations in Texas during 2015

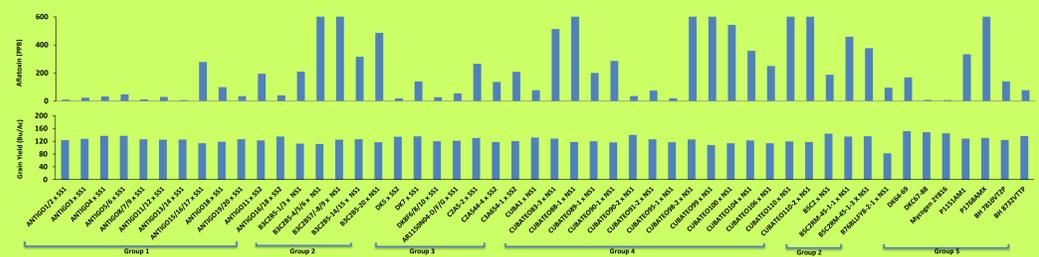

Figure 4. Average aflatoxin content (top) and grain yield (bottom) reported across diverse locations in Texas during 2014

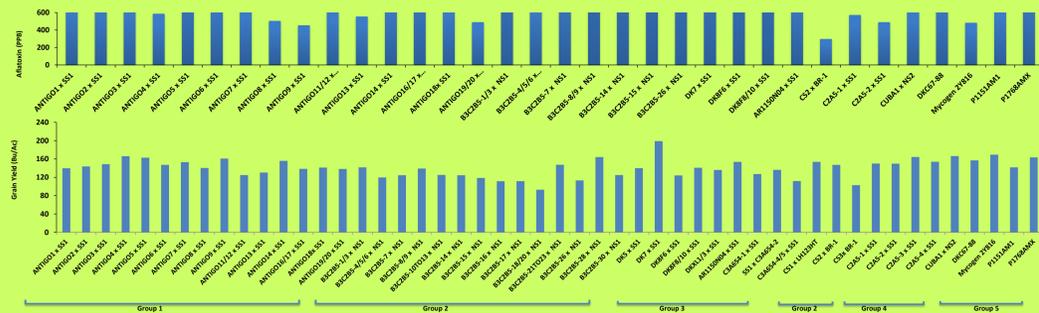

Figure 5. Location-wise grain yield of top 10 experimental hybrids and commercial checks evaluated in 2015 (top) and 2014 (bottom)

Results and Discussion

- Hybrids of the inbred lines derived from tropical x temperate corn or temperate corn x teosinte breeding population showed a wide range of maturity, variable level of aflatoxin and yield.
- Several hybrids including those made with ANTIGO-lines had good grain yield and insect resistance, and low aflatoxin level as compared to checks.
- The ANTIGO-lines were developed from the breeding cross ANTIGO:N16 and can be a useful source of aflatoxin resistance and high grain yield. ANTIGO01:N16 was developed by crossing elite temperate line with ANTIGO1, (a yellow semi-dent tropical Criollo race from Antigua).
- Early hybrids performed well in north and central Texas but not well adapted to south Texas.
- Grain yield reported from north and central region was higher than the southern part of the state and it is mainly due to presence of diverse climatic conditions across the state which affects the yield.
